## Contents

---

<b>1</b>	<b>Contents</b>	<b>3</b>
1.1	Installing hpack . . . . .	3
1.2	hpack API . . . . .	3
	<b>Index</b>	<b>7</b>

hpack provides a simple Python interface to the [HPACK](#) compression algorithm, used to compress HTTP headers in HTTP/2. Used by some of the most popular HTTP/2 implementations in Python, HPACK offers a great Python interface as well as optional upgrade to optimised C-based compression routines from [nghttp2](#).

Using hpack is easy:

```
from hpack import Encoder, Decoder

e = Encoder()
encoded_bytes = e.encode(headers)

d = Decoder()
decoded_headers = d.decode(encoded_bytes)
```

hpack will transparently use nghttp2 on CPython if it's available, gaining even better compression efficiency and speed, but it also makes available a pure-Python implementation that conforms strictly to [RFC 7541](#).

## 1.1 Installing hpack

hpack is trivial to install from the Python Package Index. Simply run:

```
$ pip install hpack
```

Alternatively, feel free to download one of the release tarballs from [our GitHub page](#), extract it to your favourite directory, and then run

```
$ python setup.py install
```

hpack has no external dependencies.

### 1.1.1 Using nghttp2

If you want to use nghttp2 with hpack, all you need to do is install it along with its Python bindings. Consult [nghttp2's documentation](#) for instructions on how to install it.

## 1.2 hpack API

This document provides the HPACK API.

**class** `hpack.Encoder`

An HPACK encoder object. This object takes HTTP headers and emits encoded HTTP/2 header blocks.

**encode** (*headers*, *huffman=True*)

Takes a set of headers and encodes them into a HPACK-encoded header block.

**Parameters**

- **headers** – The headers to encode. Must be either an iterable of tuples, an iterable of `HeaderTuple`, or a dict.

If an iterable of tuples, the tuples may be either two-tuples or three-tuples. If they are two-tuples, the tuples must be of the format `(name, value)`. If they are three-tuples, they must be of the format `(name, value, sensitive)`, where `sensitive` is a boolean value indicating whether the header should be added to header tables anywhere. If not present, `sensitive` defaults to `False`.

If an iterable of `HeaderTuple`, the tuples must always be two-tuples. Instead of using `sensitive` as a third tuple entry, use `NeverIndexedHeaderTuple` to request that the field never be indexed.

**Warning:** HTTP/2 requires that all special headers (headers whose names begin with `:` characters) appear at the *start* of the header block. While this method will ensure that happens for dict subclasses, callers using any other iterable of tuples **must** ensure they place their special headers at the start of the iterable.

For efficiency reasons users should prefer to use iterables of two-tuples: fixing the ordering of dictionary headers is an expensive operation that should be avoided if possible.

- **huffman** – (optional) Whether to Huffman-encode any header sent as a literal value. Except for use when debugging, it is recommended that this be left enabled.

**Returns** A bytestring containing the HPACK-encoded header block.

**header\_table\_size**

Controls the size of the HPACK header table.

**class** `hpack.Decoder`

An HPACK decoder object.

**decode** (*data*, *raw=False*)

Takes an HPACK-encoded header block and decodes it into a header set.

**Parameters**

- **data** – A bytestring representing a complete HPACK-encoded header block.
- **raw** – (optional) Whether to return the headers as tuples of raw byte strings or to decode them as UTF-8 before returning them. The default value is `False`, which returns tuples of Unicode strings

**Returns** A list of two-tuples of `(name, value)` representing the HPACK-encoded headers, in the order they were decoded.

**Raises** `HPACKDecodingError` – If an error is encountered while decoding the header block.

**header\_table\_size**

Controls the size of the HPACK header table.

**class** `hpack.HeaderTuple`

A data structure that stores a single header field.

HTTP headers can be thought of as tuples of `(field name, field value)`. A single header block is a sequence of such tuples.

In HTTP/2, however, certain bits of additional information are required for compressing these headers: in particular, whether the header field can be safely added to the HPACK compression context.

This class stores a header that can be added to the compression context. In all other ways it behaves exactly like a tuple.

**class** `hpack.NeverIndexedHeaderTuple`

A data structure that stores a single header field that cannot be added to a HTTP/2 header compression context.

**class** `hpack.HPACKError`

The base class for all `hpack` exceptions.

**class** `hpack.HPACKDecodingError`

An error has been encountered while performing HPACK decoding.

**class** `hpack.InvalidTableIndex`

An invalid table index was received.

## D

`decode()` (*hpack.Decoder method*), 4  
`Decoder` (*class in hpack*), 4

## E

`encode()` (*hpack.Encoder method*), 3  
`Encoder` (*class in hpack*), 3

## H

`header_table_size` (*hpack.Decoder attribute*), 4  
`header_table_size` (*hpack.Encoder attribute*), 4  
`HeaderTuple` (*class in hpack*), 4  
`HPACKDecodingError` (*class in hpack*), 5  
`HPACKError` (*class in hpack*), 5

## I

`InvalidTableIndex` (*class in hpack*), 5

## N

`NeverIndexedHeaderTuple` (*class in hpack*), 5
